ACKNOWLEDGMENTS

This investigation was funded by the U.S. Geological Survey (USGS) Branch of Coal Resources. Special thanks go to Ed Landis for his assistance with overall project development and to Bob Hobbs for technical information on drilling and geophysical logging. Ricke Smith was helpful in implementing the National Coal Resources Data System (NCRDS) and in generating maps and resource calculations. Other USGS Branch of Coal Resources personnel who helped with the NCRDS were Dorsey Blake, Bruce Barnum, and Court Williamson. Tom Major of the Water Resource Division assisted in providing valuable data on water wells.

Colorado Geological Survey people who contributed their efforts to the project include the following: L.R. Ladwig, Chief, Mineral Fuels Section provided overall guidance; Jennifer Caine, Charles Campbell, Tom Lorenson, Susan Aumiller, and Dave Genova made significant contributions to various phases in assimilating data; Bruce Kelso assisted with field work; Cheryl Brchan supervised the drafting; and Valerie Taylor-Pierce, Chris Avila, Brenda Richardson and Betty Jones typed the manuscript.

John Romero, Colorado Division of Water Resources, provided valuable information on Denver Basin stratigraphy; Tom Bretz, Colorado State Land Board, aided in our acquisition of required permits; and Bob Puterski, Colorado Division of Local Affairs, assisted with computer applications.

Valuable assistance was provided by many individuals in private industry who remain anonymous due to the proprietary nature of the information they provided. Milt Childers and Gary Lund of Power Resources Corporation were extremely cooperative, and made public a tremendous amount of information from the southern part of the Denver Basin (from a joint Powerco/Shell Oil Corporation drilling program). Dave Germer of Rocky Mountain Energy (RME) was very helpful with general advice, and RME provided a large amount of proprietary information. Willard Owens allowed access to his extensive well log files, providing some information not available elsewhere.

INTRODUCTION

This report is the result of a cooperative investigation conducted by the Colorado Geological Survey (CGS) and funded by U.S. Geological Survey (USGS) Grant No. 14-08-0001-A0086. It is part of a nationwide program sponsored by the USGS to assess the quality and quantity of the nation's coal resources, as authorized by the Federal Coal Leasing Amendments Act of October 1975. This report presents the findings of an investigation entitled "Exploratory Coal Drilling and Coring Program in the Castle Rock 1/2° x 1° Quadrangle, Colorado".

The primary goal of the investigation is to evaluate the coal resources in the approximately 1900 mi^2 (4920 km^2) Castle rock 1/2° x 1° quadrangle, and an additional 200 mi^2 (520 km^2) east into the Limon 1/2° x 1° quadrangle to include the eastern part of the Denver coal basin. The study area is located between latitude 39° and 39° 30'N and longitude 103° 48' to 105°W. Throughout this report the terms Castle Rock quadrangle and quadrangle are intended to include the extended study area. The study area includes parts of Elbert, Douglas, and El Paso Counties (fig. 1). The study area lies within the Denver basin in the Great Plains Physiographic Province of the Interior Plains (Fenneman, 1931). A generalized stratigraphic column of rocks from Late Cretaceous through the Eocene in age is presented in figure 2. The Upper Cretaceous Laramie and Upper Cretaceous and Paleocene Denver Formations contain the only appreciable quantities of coal within the quadrangle.

The evaluation was compiled from existing data, including drillers' and geophysical logs from coal exploratory drill holes, uranium exploratory drill holes, water wells, oil and gas wells drilled by numerous individuals and companies, and published and unpublished reports. Sources of data include the Colorado Division of Water Resources and USGS Water Resources Division (water well information), the Colorado Oil and Gas Conservation Commission and Petroleum Information Corporation (oil and gas well logs), the Colorado State Land Board (various logs from drill holes on state property), and private industry (exploratory drill holes). To obtain additional information on coal depth and thickness, the CGS conducted a program to geophysically log water wells in the study area (Eakins, 1981). To obtain information on coal quality and stratigraphy, a drilling and coring program was implemented (Eakins and others, 1983). Proprietary information is deleted on published versions of this report. The location, elevation and total depth of all non-proprietary drill holes used in this report is shown in table 1, organized by source.

Our nation's expanding energy demands require that a detailed knowledge of our coal resources be available for energy planning. The identification and classification of these coal resources will aid in land use decisions, which will help to optimize resource recovery.

The bedrock geology of the study area is depicted in figure 3. The geography and geology of the area are further discussed in Kirkham and Ladwig (1979) and Romero (1976).

LARAMIE FORMATION COAL ZONE

The Laramie Formation coal zone underlies the entire quadrangle except for the extreme southwestern corner where the coal crops out. The coal zone reaches a maximum depth of about 2800 ft (850 m) along the basin axis in the western third of the quadrangle. Data points are scarce in the western half of the quadrangle, making correlation of the coal zone difficult. Correlation of the coal was based in part on reliable water well and oil and gas well logs. The general stratigraphy of the Laramie Formation in the Buick-Matheson area is shown in figure 4.

The stratigraphy of the Laramie Formation coal zone is complex and changes significantly across the quadrangle. This results from the environment in which these coals were deposited. The Laramie Formation coal zone was deposited with a delta-plain facies in channels, levees, splays, swamps and lakes (Kirkham and Ladwig, 1979). The coals developed primarily in poorly drained swamps in overbank areas adjacent to the channel-margin facies (Weimer, 1973).

Coal distribution and stratigraphy in the Laramie Formation coal zone can be interpreted through the use of deltaic sedimentation models. Areas which don't contain coal were probably channel and channel-margin environments. Sandstones were deposited in channel environments while light gray, massive claystones were deposited in the well-drained swamps, and light-colored silts and clays were deposited on the levees. Peat and dark gray, organic rich claystone were deposited in the poorly drained swamps in overbank areas and occasionally in abandoned channels. Fine to medium-grained sandstones were deposited in overbank areas when crevasse splays broke through the levees (Kirkham and Ladwig, 1979).

Extreme depths to the Laramie Formation coal zone placed limitations on drilling in much of the quadrangle, especially in the western half of the quadrangle. On the western flank of the basin extremely high dips precluded drilling, and sparse outcrop and no exploration data is available. Drilling through the Laramie coal zone by the Colorado Geological Survey was concentrated in the Buick-Matheson area as shown on plate 1. Several CGS holes were rotary drilled through the Laramie Formation coal zone where the coal zone exceeded 1,000 ft (300 m) in depth, west of the Buick-Matheson area. Information on non-proprietary data points for the Laramie Formation coal zone and individual beds is presented in tables 2-A through 2-E.

Two coal beds occur within the lower part of the Laramie Formation in the Buick-Matheson area. These are called the A and B beds. The A coal bed splits locally into the Upper A and Lower A beds, where the thickness of the parting exceeds the thickness of the thinner of the coal bed splits. In this quadrangle the base of the Laramie Formation coal zone is defined as the top of the transition zone between the Laramie and the underlying Upper Cretaceous Fox Hills Sandstone. The transition zone was chosen because of the difficulty in picking the contact between the Laramie Formation and the Fox Hills Sandstone on geophysical logs. The prominent sandstone at the top of the transition zone is the only readily distinguishable unit with which to define the base of the Laramie Formation coal zone. The A coal bed, or Lower A coal bed where the A coal bed is split, is located from 0 - 15 ft (0 - 5 m) above the top of the transition zone. The Upper A coal bed occurs 10 - 35 ft (3 - 10 m) above the Lower A coal bed, where the A coal bed is split. The B coal

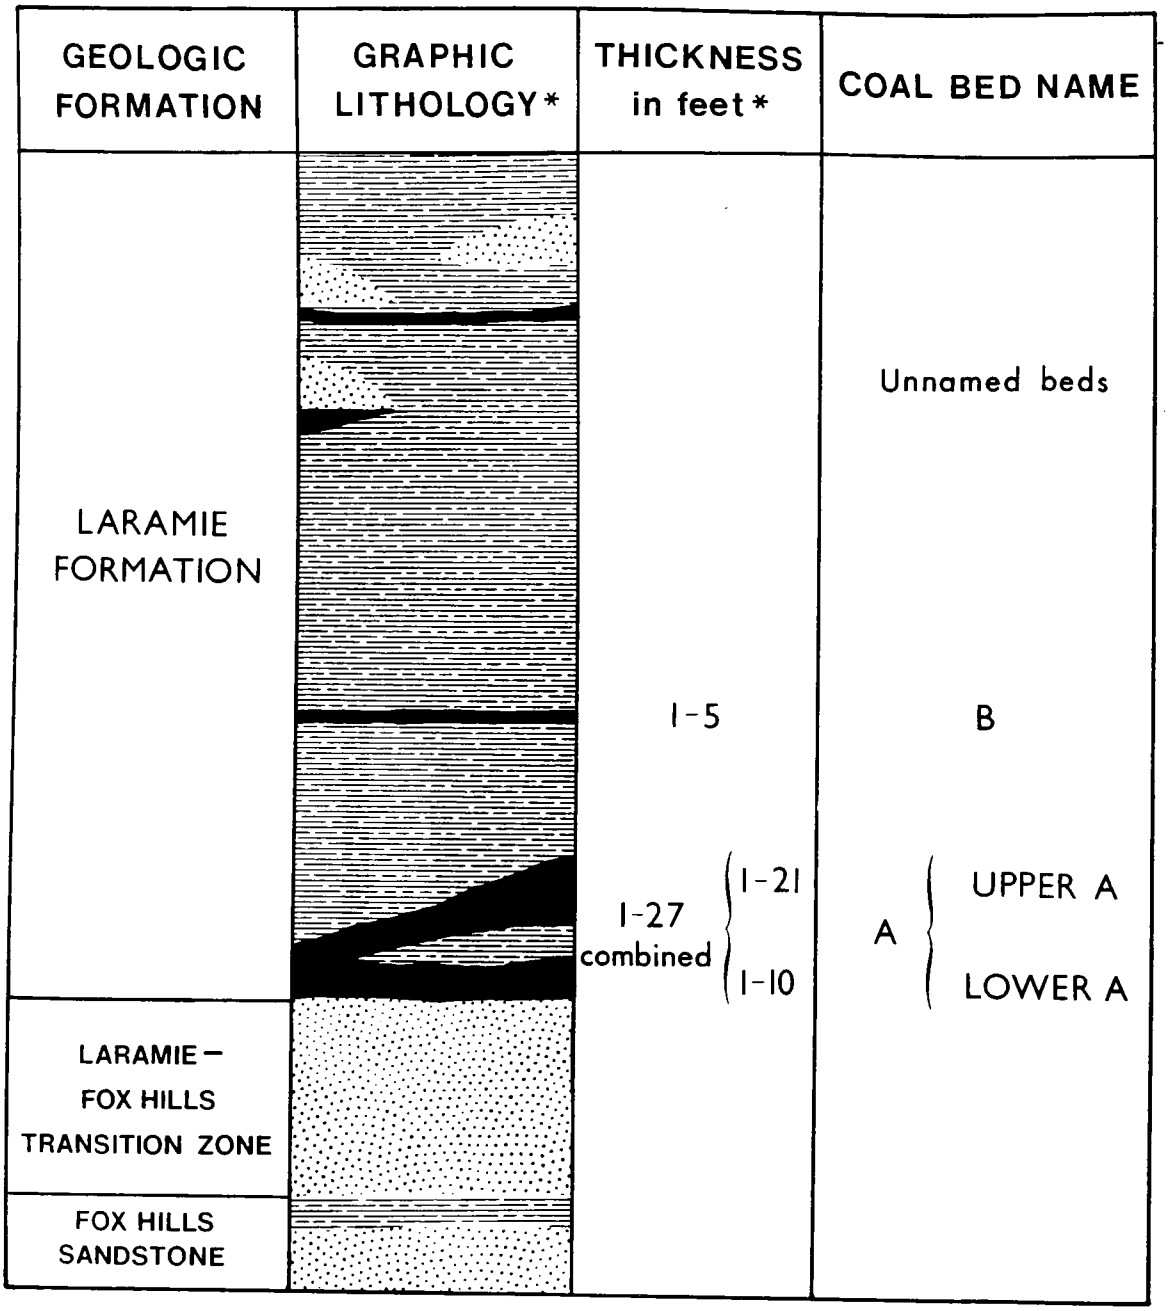

Figure 4. Generalized stratigraphy of the Laramie Formation.

bed is located 15 - 50 ft (5 - 15 m) above the A coal bed, or Upper A coal bed where the A coal bed is split, and generally marks the top of the Laramie Formation coal zone in the study area. Thin coals of little economic significance are commonly found above the B coal bed.

Mapping of the Laramie Formation coal zone was restricted by the extent to which coal beds could be correlated. In the eastern part of the study area where depths to Laramie Formation coal beds are generally shallow and drill hole data is relatively abundant, correlation of individual beds was possible. This area, which extends from the coal outcrop on the east side to an arbitrary line on the west beyond which correlation is speculative, is called the Buick-Matheson area. To the west of the Buick-Matheson area, coal beds within the Laramie Formation coal zone have been combined for mapping purposes. Plate 2 shows the total or cumulative thickness of coal in this area and plate 3 is a map of the structure and overburden thickness of the coal zone. Plates 4 through 7 contain structure contour and isopach maps of the four correlated coal beds within the Buick-Matheson area, the A, Upper A, Lower A and B coal beds. The boundary between the area mapped as the A coal bed and the area mapped as the Upper A and Lower A coal beds is delineated by a split line. This line represents points for which the thickness of the parting equals the thickness of the thinner of the two coal bed splits. Therefore, the A coal bed is only mapped in areas where the Upper A and Lower A coal beds are not located, and vice versa. The overburden thickness of the A coal bed, or Upper A coal bed where the A coal bed is split, is mapped on plate 4-C. Lateral changes in the coal beds are depicted on these maps and in addition on cross sections shown on plate 8. Plate 7 is an index map of cross section locations.

Samples of the A coal bed taken from two holes that penetrated the Laramie Formation show an apparent rank of Lignite A, with as-received heat of combustion values ranging from 6773 - 7259 Btu/lb, and as-received sulfur contents of about 0.3 percent (Eakins, 1983). Other analyses of Laramie Formation coals are available in Kirkham (1978b). These show similar analytical values of approximately 7,000 Btu/lb for as-received heat of combustion and less than 1.0 percent sulfur.

Economic development of Laramie Formation coal will be based on such factors as bed thickness, Btu value of the coal, overburden thickness, demand, and environmental considerations. Based on available data, Laramie Formation coal in the Buick-Matheson area appears to be more suitable for surface and/or underground mining than the remainder of the quadrangle. In this area, overburden is generally less than 200 ft (60 m) thick and coal bed thicknesses exceed 10 ft (3 m). As shown on plates 4 through 7 and tables 3-B through 3-E, the most promising areas within the Buick-Matheson area for surface mining are within ranges 58 and 59 west. In-situ gasification of Laramie Formation coal may be possible in areas where coal beds exceed 10 ft (3 m) in thickness and overburden thickness range from about 500 to 1500 ft (150 to 450 m) (see plates 3, 4C). Townships 7 and 8 south, range 60 west are the most likely to contain Laramie Formation coal beds in this category, as shown on plates 2 and 3 and table 3-A. Other areas may be suitable for in-situ gasification, but present information is not sufficient to warrant their delineation. Plate 2 shows the cumulative coal thickness within the Laramie Formation coal zone, so individual beds greater than 10 ft thick are not shown. See table 2-A for information on individual bed thicknesses.

Insignificant amounts of coal have been mined from the Laramie Formation in the study area, therefore depletion was not considered in the resource calculations. For depletion data see Boreck and others (1979). Total Laramie Formation coal resources within the study area are estimated to be 21 billion tons (see tables 3-A to 3-E and table 3-K).

DENVER FORMATION

Coal occurs throughout the vertical extent of the Denver Formation, with thicker coal beds concentrated in the upper half. It accumulated in early Tertiary swamps east of the Front Range (Kirkham and Ladwig, 1979). The depositional environment is poorly understood. The nearly barren area between the northern and southern lignite areas of Kirkham and Ladwig (1979) and the thinning and pinching out of coal beds westward toward the basin axis might possibly be explained by the depositional model proposed by Goolsby (1983) and Smith and Putnam (1980) of an anastomosing fluvial system.

The Ramah-Fondis area is the primary coal-bearing area of the Denver Formation in the study area. The coal is nearest the surface and apparently thickest in this area, as delineated by a large number of drill holes. Further west the Denver Formation is overlain by a progressively greater amount of overburden. The western edge of the Ramah-Fondis area is based upon the extent the Denver Formation coal could be correlated which is controlled in part by the density of drill hole information. The eastern edge of the Ramah-Fondis area is the Denver Formation coal zone outcrop.

Denver Formation coal zone names used in this report were adapted from coal bed names used in CGS Resource Series 5 (Kirkham and Ladwig, 1979). The Denver Formation coal area of the Castle Rock quadrangle is equivalent to the southern lignite area of Kirkham and Ladwig (1979) with the addition of areas containing coal with thicker overburden in the western part of the study area.

The Wolf, Comanche, and Bijou coal zones are at the same stratigraphic level as the coal beds of the same names used by Kirkham and Ladwig (1979), except in some cases they include more than one bed of mappable thickness. Other coal beds less than 2.5 ft thick occur between and below the named coal zones, and have not been included because they are not considered of economic significance. The Kiowa coal zone contains the Upper, Middle, and Lower Kiowa coal beds of Kirkham and Ladwig (1979) grouped into one coal zone for mapping convenience and because of questionable coal bed correlations.

The Denver Formation coal beds of the Denver East quadrangle, described in Brand and Eakins (1981), are generally stratigraphically higher than the beds mapped in this report. The following coal correlations are tentative and further drilling is needed for verification. The Lowry coal bed of Brand and Eakins (1981) crops out north of the Castle Rock quadrangle. The Bennett coal bed is equivalent to the Wolf coal zone and the Watkins coal bed is equivalent to the Comanche coal zone. The Kiowa and Bijou coal zones are stratigraphically lower than the named and mapped coal beds of Brand and Eakins (1981). Minor coal beds occur below the Bijou coal zone, however a lack of data makes detailed coal correlations difficult.

Mapping of the coals in the Denver Formation was restricted by the extent of coal zone correlations. In the Ramah-Fondis area, where depths to the coal zones of the Denver Formation are generally shallow and drill hole data is

relatively abundant, correlation of individual coal zones was possible. To the west of the Ramah-Fondis area, coal zones within the Denver Formation have been combined for mapping purposes. Plate 9 shows the total or cumulative thickness of coal in this area and plate 10 is a map of the structure and overburden thickness of the top coal zone within the Denver Formation in this area. Plates 11 through 14 contain structure contour and isopach maps of the four coal zones within the Denver Formation in the Ramah-Fondis area, the Bijou, Kiowa, Comanche and Wolf coal zones. Plate 13-C is a map of the overburden thickness of the Comanche coal zone and is indicative of the overburden above the other zones, which is not included in this report. Lateral changes in the coal zones are depicted on these maps and in addition on cross sections shown on plates 15-17. Plate 7 is an index map of cross section locations.

The thickness of the coal zones in the Denver Formation is extremely variable due to the lenticularity of the beds. As shown on figure 4, all the coal zones have minimum thicknesses of a foot (or less). The maximum thicknesses at drill holes for each are: Bijou, 19 ft, Kiowa, 30 ft, Comanche, 26 ft and Wolf, 29 ft. These are isolated measurements and average thicknesses are much lower. Interburden thicknesses also vary considerably, The Kiowa coal zone - Bijou coal zone interval ranges from about 30 to 80 ft in thickness, the Comanche coal zone - Kiowa coal zone interval ranges from about 20 to 150 ft in thickness and the Wolf coal zone - Comanche coal zone interval ranges from about 35 to 100 ft in thickness.

A large portion of coals of the Denver Formation lie within 200 ft (60 m) of the surface and are well suited for surface mining. These surface-mineable coals are located primarily within ranges 61 and 62 west, as shown on plates 11 through 14 and tables 3-G through 3-J. In many cases more than one coal bed or zone could be surface mined during the same operation, because of the typically small amount of interburden between beds and zones. In areas where overburden exceeds 200 ft (60 m) and beds exceed 10 ft (3 m) in thickness in-situ gasification is possible. For in-situ gasification, overburden thickness should exceed 500 ft (150 m) to avoid subsidence problems and be less than 1500 ft (460 m) due to economic constraints (Glass, 1983). The primary area which appears to be suitable for in-situ gasification is just west of the Ramah-Fondis area in townships 7 through 9 south, range 63 west.

Five coal samples were collected from three holes that were drilled by the CGS and penetrated the Denver Formation. Analyses of the coal show the following results: an apparent rank of lignite A, as-received heat of combustion values ranging from 4829 - 5566 Btu/lb and as-received sulfur contents averaging 0.35 percent, ranging from 0.29 - 0.87 percent (Eakins, 1983). Other analyses for coals in this area are included in Kirkham (1978b).

Denver Formation coal contains many partings, most of which are composed of clay and carbonaceous clay. Some partings are composed of kaolinite that contains more than 25 percent alumina (Kirkham and Ladwig, 1979). Extraction of these alumina-rich partings could be economically feasible (Kirkham and Ladwig, 1979).

Depletion of Denver Formation coal due to previous mining is negligible and was not considered in the resource calculations. See Boreck and Murray (1979) for depletion data on this quadrangle. Total coal resources in the Denver Formation within the study area are estimated to be about 21 billion tons (see tables 3-F to 3-K).

GEOLOGIC FORMATION	GRAPHIC LITHOLOGY*	THICKNESS in feet *	COAL ZONE NAME

COMPUTER METHODS

The maps and tables in this report are derived from computer-generated output from the National Coal Resources Data System (NCRDS). All data collected, including proprietary data, was entered into the NCRDS after correlations were established. The data base, which included previously entered data, was then searched using the PACER program, for coal beds or coal zones 2.5 ft (0.8 m) or more thick before mapping the coal. Outcrop/subcrop and overburden lines were digitized and entered into the computer system. Isopach and structure maps were generated using the GARNET program. A grid size of 0.3 miles was used in the computer mapping. GARNET was used to calculate coal resources which were retyped as presented in tables 3A-K. Table 1, showing basic drill hole data, was generated using PACER.

The computer mapping is based upon values calculated for grid cells and individual point values are not honored. In some cases the drill hole data conflicts with map isolines to a small extent. With a 0.3 mile grid cell size, this problem rarely occurred. To alleviate the problem isolines were generally shifted somewhat by redrafting to compensate for this discrepancy. Considerable redrafting was required to prepare the maps for publication. Some of the isolines generated by the computer exhibit erratic non-smoothness in areas remote from drill hole control. These have been redrafted in some cases to give the maps a better appearance. Line labels were hand drafted and many drill hole labels we redrafted due to problems with overprinting. The overburden maps were hand drafted, although digitized overburden maps were used for computer resource calculations.

RESOURCE CALCULATIONS

Some assumptions were made in manipulating coal data for mapping and resource calculation which require explanation. Coal data is scarce for the Denver Formation and the Laramie Formation in the western part of the quadrangle because of the increase in coal zone depth from east to west. Therefore, correlation of the coals was not possible for large portions of the study area. Separate maps for correlated and uncorrelated areas are presented for both formations. The western limit of the Denver Formation is poorly defined by available data. Where the entire formation is not represented in the drill hole logs, isopach maps and structure contour maps may not shown the true character of the coal zones.

The Laramie Formation coal zone has a higher density of data points than does the Denver Formation coal zone in the western part of the quadrangle. These data points are almost exclusively from oil and gas exploratory drill holes, which in most cases have only spontaneous potential and resistivity logs for lithologic determination (some had gamma gamma density logs). The Laramie Formation coal zone can be identified on the logs and some of the better logs were interpreted for coal bed thickness and structure. Errors in coal thickness determinations from oil and gas logs may be significant in some cases, on the order of several feet, therefore resource estimates in the vicinity of these data points should be considered preliminary.

Resource estimate categories are based on USGS Circular 891 (Wood and others, 1983). A great deal of proprietary data was used in this study. In order to preserve the confidentiality of drill hole locations, measured and indicated coal resource reliability categories are combined and considered demonstrated

coal resources. The reliability categories are determined by the distance of the coal resources from a data point. Demonstrated resources (shown as D on tables 3-A to 3-J) include coal resources calculated within a radius of 0 - .75 (0 - 1.2 km) from a data point, inferred resources (I) include coal resources calculated within a radius of .75 - 3.0 mi (1.2 - 4.8 km) from a data point, and hypothetical resources (H) include coal resources calculated in the area greater than 3.0 mi (4.8 km) from a data point. The resources are tabulated by township and range within each county for each coal zone or coal bed. For each of the above geographic boundary categories, coal resources are tabulated by overburden thickness and coal thickness categories. Overburden thickness categories used are 0-200 ft, 200-500 ft, 500-1000 ft, 1000-2000 ft and 2000 plus ft. Along the western side of the study area a 200 ft overburden line could not be accurately determined, so a 0-500 ft overburden thickness category was used. Coal thickness categories used are 2.5-5 ft, 5-10 ft and 10 plus ft. The average thickness shown in tables 3-A to 3-K is a weighted average. Where coals are not correlated, tables 3-A and 3-F, resources are calculated for cumulative coal thickness. Tables 3-B through 3-E tabulate coal resources of the individual coal beds in the Laramie Formation. Tables 3-G through 3-J tabulate the resources for correlated coal zones in the Denver Formation, which are derived from cumulative coal thicknesses. The coal resource tables, 3-A through 3-K were generated from GARNET and have been recompiled and totaled, then entered onto a word processor to obtain the final format.

Previous coal resource estimates within the study area were done by Landis (1971) and Speltz (1976). In his report on Colorado coal resources, Landis only estimated coal resources for 11 townships within the study area. They are stated to contain about 1.04 billion tons of coal, about 500 million tons from the Buick-Matheson area and about 550 million tons from the Ramah-Fondis area. The Speltz report gives an estimate of the total identified strippable coal within Colorado. For the Denver Basin these are subdivided only by township and range. Since the study area boundaries are within townships it is not possible to precisely assign his estimates to the study area. Within 33 townships, Speltz estimates about 3.75 billion tons of coal. In this report, a total of about 42.81 billion tons of coal are estimated for the entire study area. Table 3-K is a summary of the coal resource information in tables 3-A through 3-J, in which the resources are totaled by county within each overburden and thickness category and by reliability category. Douglas County contains about 2.82 billion tons of Denver Formation coal and 4.47 billion tons of Laramie Formation coal, or a total of about 7.29 billion tons. In El Paso County there are estimated to be 2.65 billion tons of coal in the Denver Formation, 4.63 billion tons in the Laramie Formation and a total of 7.28 billion tons. Elbert County contains about 15.83 billion tons of Denver Formation coal, 12.41 billion tons of Laramie Formation coal, or a total of about 28.24 billion tons. At depths of 0-200 ft there are about 6.41 billion tons of Denver Formation coal and 2.37 billion tons of Laramie Formation coal within the study area.

CONCLUSIONS

Coal resource estimates in this report are higher than those reported in previous coal resource studies for the same area. A more complete data base was used for this study; however, for large areas the estimates are hypothetical and therefore uncertain. Future mining in the study area will depend upon many complex and interrelated factors, some of which lie beyond the scope of this report, such as political, economic and environmental considerations.

Surface and/or underground mining of Laramie Formation coal will be limited to portions of the Buick-Matheson area. In-situ gasification of thick, 10 ft (3 m) or greater, Laramie Formation coals may be possible where the coal cannot be mined by conventional methods, provided that the thickness of the overburden, coal thickness, and other factors are favorable. Most of the coal in the Laramie Formation is too deep or too thin for economical recovery using present methods.

Denver Formation coal is surface-mineable in a significant part of the Ramah-Fondis area because overburden is relatively thin and coal beds are relatively thick. Multiple bed mining may be feasible in certain areas. Poor quality and numerous clay partings within the coal beds may limit their exploitation. Much of the coal that is unsuitable for surface mining may be utilized for in-situ gasification.

Table 3-A. Laramie Formation coal zone resources.

Coal resources in the Laramie Formation coal zone in the Castle Rock 1/2° X 1° quadrangle, Colorado, as of Nov. 1, 1984. [Calculations are in millions of short tons; to convert feet to meters multiply by 0.3048, to convert short tons to metric tons multiply by 0.9071; Laramie Formation coal zone is in the Cretaceous Laramie Formation; average thickness is a weighted average.]

Table 3-B. A coal bed resources.

Coal resources in the A coal bed in the Castle Rock 1/2° X 1° quadrangle, Colorado, as of Nov. 1, 1984.
[Calculations are in millions of short tons; to convert feet to meters multiply by 0.3048, to convert short tons to metric tons multiply by 0.9071; A coal bed is in the Cretaceous Laramie Formation; average thickness is a weighted average.]

Table 3-E. B coal bed resources.

Coal resources in the B coal bed in the Castle Rock 1/2° X 1° quadrangle, Colorado, as of Nov. 1, 1984.
[Calculations are in millions of short tons; to convert feet to meters multiply by 0.3048, to convert short tons to metric tons multiply by 0.9071; B coal bed is in the Cretaceous Laramie Formation; average thickness is a weighted average.]

Table 3-F. Denver Formation coal zone resources.

Coal resources in the Denver Formation coal zone in the Castle Rock 1/2° X 1° quadrangle, Colorado, as of Nov. 1, 1984. [Calculations are in millions of short tons; to convert feet to meters multiply by 0.3048, to convert short tons to metric tons multiply by 0.9071; Denver Formation coal zone is in the Cretaceous/Paleocene Denver Formation; average thickness is a weighted average.]

Table 3-G. Wolf coal zone resources.

Coal resources in the Wolf coal zone in the Castle Rock 1/2° X 1° quadrangle, Colorado, as of Nov. 1, 1984.
[Calculations are in millions of short tons; to convert feet to meters multiply by 0.3048, to convert short tons to metric tons multiply by 0.9071; Wolf coal zone is in the Cretaceous/Paleocene Denver Formation; average thickness is weighted average.]

Table 3-H. Comanche coal zone resources.

Coal resources in the Comanche coal zone in the Castle Rock 1/2° X 1° quadrangle, Colorado, as of Nov. 1, 1984. [Calculations are in millions of short tons; to convert feet to meters multiply by 0.3048, to convert short tons to metric tons multiply by 0.9071; Comanche coal zone is in the Cretaceous/Paleocene Denver Formation; average thickness is a weighted average.]

Table 3-I. Kiowa coal zone resources.

Coal resources in the Kiowa coal zone in the Castle Rock 1/2° X 1° quadrangle, Colorado, as of Nov. 1, 1984. [Calculations are in millions of short tons; to convert feet to meters multiply by 0.3048, to convert short tons to metric tons multiply by 0.9071; Kiowa coal zone is in the Cretaceous/Paleocene Denver Formation; average thickness a weighted average.]

Table 3-J. Kiowa coal zone resources.

Coal resources in the Bijou coal zone in the Castle Rock 1/2° X 1° quadrangle, Colorado, as of Nov. 1, 1984. [Calculations are in millions of short tons; to convert feet to meters multiply by 0.3048, to convert short tons to metric tons multiply by 0.9071; Bijou coal zone is in the Cretaceous/Paleocene Denver Formation; average thickness a weighted average.]

Table 3-K. Summary of total coal resources.

Coal resources in the Denver Formation and Laramie Formation coal zones in the Castle Rock 1/2° X 1° quadrangle, Colorado, as of Nov. 1; 1984. [Calculations are in millions of short tons; to convert feet to meters multiply by 0.3048, to convert short tons to metric tons multiply by 0.9071; Denver Formation coal zone is in the Cretaceous/Paleocene Denver Formation; Laramie Formation coal zone is in the Cretaceous Laramie Formation; average thickness is a weighted average.]

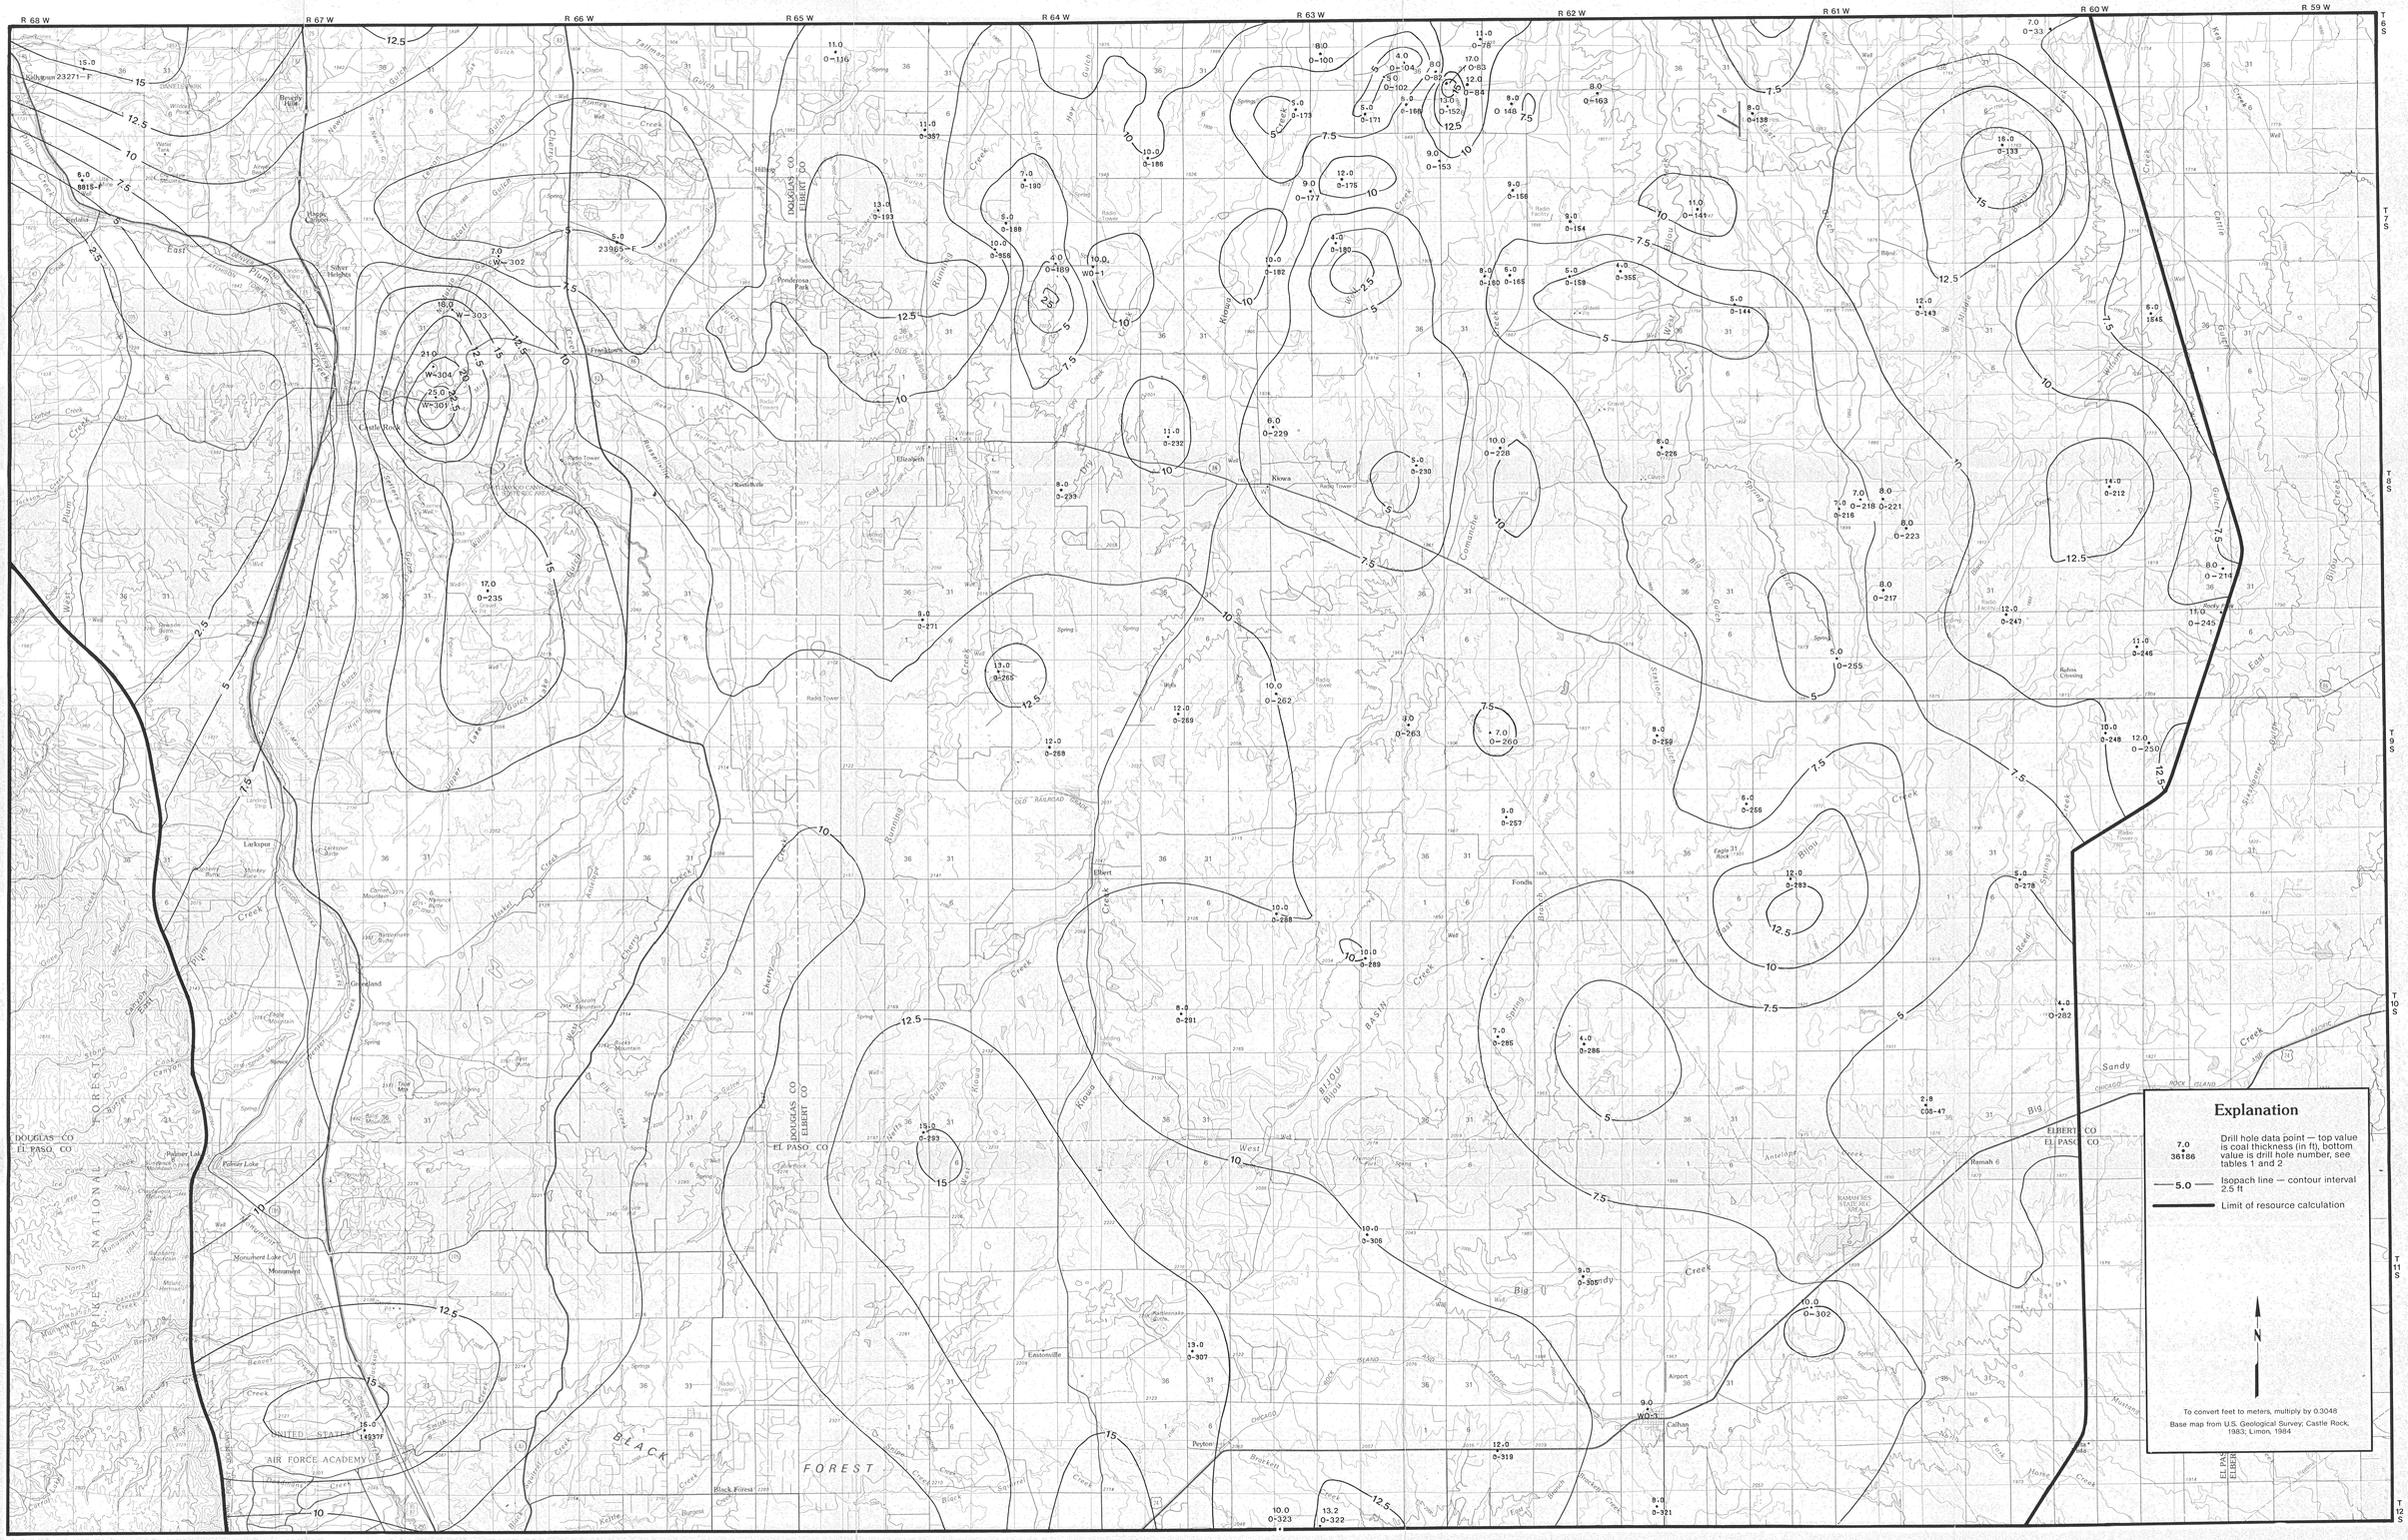
COAL RESOURCES OF THE CASTLE ROCK 1/2° × 1° QUADRANGLE AND ADJACENT AREA, COLORADO

by Wynn Eakins and Margaret S. Ellis



Explanation

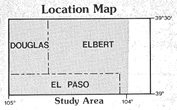
- 7.0 / 36186 — Drill hole data point — top value is coal thickness (in ft), bottom value is drill hole number, see tables 1 and 2
- —5.0— Isopach line — contour interval 2.5 ft
- Limit of resource calculation

To convert feet to meters, multiply by 0.3048

Base map from U.S. Geological Survey, Castle Rock, 1983, Limon, 1984

ISOPACH MAP OF TOTAL COAL IN THE LARAMIE FORMATION COAL ZONE, WEST OF THE BUICK-MATHESON AREA

Location Map



This report is the result of a cooperative investigation conducted by the Colorado Geological Survey and funded by U.S. Geological Survey Grant No. 14-08-001-A0086.

Explanation

- 5491.0 / CGS-43 — Drill hole data point — top value is top of coal elevation (in ft), bottom value is drill hole number; see tables 1 and 2
- 5500 — Structure contour line — contour interval 100 ft
- 500 — Overburden isopach line — 200, 500, 1000 and 2000 ft lines
- Limit of resource calculation

To convert feet to meters, multiply by 0.3048

Base map from U.S. Geological Survey; Castle Rock, 1983; Limon, 1984

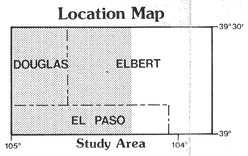
SCALE 1:100 000

1 ½ 0 1 2 3 4 5 MILES

1 .5 0 1 2 3 4 5 KILOMETERS

STRUCTURE CONTOUR AND OVERBURDEN ISOPACH MAP ON THE COAL ZONE IN THE DENVER FORMATION, WEST OF THE RAMAH-FONDIS AREA

Location Map



This report is the result of a cooperative investigation conducted by the Colorado Geological Survey and funded by U. S. Geological Survey Grant No. 14-08-001-A0086.

CROSS SECTIONS I-I' THROUGH K-K' SHOWING THE COAL BEARING INTERVAL OF THE DENVER FORMATION, RAMAH-FONDIS AREA

EXPLANATION

DX-190 Drill hole number

Sand or Sandstone

Shale

Coal

Lithology unknown

Horizontal scale 1:100,000
Vertical scale 1:1,200
Vertical Exaggeration 1:83.3

NOTE: Certain lithologies are unavailable due to information source.

Dashed lines indicate uncertain correlations.

Elevations are in feet. To convert feet to meters, multiply by 0.3048.

Horizontal scale and vertical exaggeration are approximate.
